ABSTRACT

Caffeine is a methylxanthine alkaloid with purine structure, it acts on the central nervous system (CNS). It is chemically related to adenine and guanine basis of DNA and RNA respectively. Caffeine containing drinks such as tea, coffee and cola are consumed globally in high volumes. Caffeine has both positive and negative health effects. It may have a small preventive effect against certain disorders including Parkinsons diseases. Some people experience sleep disruption or anxiety when they consume caffeine, also it can cause a moderate forms of drug dependence. This article focuses on the effect of caffeine in human body.

KEY WORDS Caffeine, tea powder, health issues

INTRODUCTION

The most popular and extensively utilized soft drinks in homies is tea regarded as the most commonly used psychoactive drug. Tea with a modest caffeine content seem to enhance cognitive function. According to FDA, caffeine is a food as well as a drug. Over consumption of caffeine may cause many health problems.

CHEMICAL STRUCTURE AND CHARACTERISTICS OF CAFFEINE

CHEMICAL STRUCTURE

Caffeine (C₈H₁₀N₄O₂) also known as 1,3,7 trimethylxanthine, is a methylxanthine alkaloid. Many plants and trees produce it, along with its precursor theobromine, to defend themselves from illness and predators. In terms of structure, these substances are carbon and

nitrogen-based molecules composed of two purine rings, a pyrimidine ring (C5 ring) and a imidazole ring (C6 ring), both of which two nitrogen atoms.

CAFFEINE (1- ethyl-3, 7-dimethyl-3,7-dihydro-1*H*- purine-2,6- dione)

CHARACTERISTICS

Caffeine is odourless and has a distinct bitter taste . It is a white powder with a density of 1.23 that is mildly soluble in organic solvents and water. However, its solubility in water increases significantly at higher temperature (1% w/w) at 15 and 10% at 60. The melting point is 234-239, and the sublimation temperature at atmospheric pressure is 178 .Caffeine is a very weak base that reacts with acids to form easily hydrolyzed salts and is relatively stable in dilute acids and alkalies. Caffeine reacts with acids to generate unstable salts which are destroyed by strong caustic alkaline solutions. Caffeine has a UV absorption spectrum that peaks at 274nm and has an absorption coefficient of 9700 in aqueous solution.

EFFECTS OF CAFFEINE IN HUMAN BODY

MECHANISM OF ACTION

Caffeine mode of action is complicated because it affects multiple body systems. A plausible mechanism involves the inhibition of adenosine receptors, nucleotide phosphodiesterase enzymes, calcium handling inside cells and also involved in adenosine receptor antagonism. Through their effects on the second messengers cAMP and cGMP,

phosphodiesterase enzymes control cell activity. By activating hormone sensitive lipases, this results in lipolysis and the release of glycerol and fatty acids.

USES OF CAFFEINE

Caffeine is a stimulant it makes your nervous system and brain function more actively. Additionally, it promotes body's circulation of hormones like adrenaline and cortisol. Caffeine can help you feel focused and energized in low quantities. Low moderate doses (50-300 mg) may promote alertness, energy and concentration. However, the studies related to caffeine seems to indicate that it has certain health benefits.

Caffeine produces various benefits on illness such as, auto immune diseases, immunomodulation and ocular, respiratory, neurodegenerative diseases.

- **Anti-inflammatory disease**

In most cases, inflammation is triggered by an injection or tissue injury. Caffeine has the ability to modulate the immunological system.

- **Ocular diseases**

Along with choroid and choroidal cells, retinal endothelium and retinal pigment endothelial cells (RPE) also express adenosine receptors. Caffeine may therefore potentially be effective in treating eye conditions such as retinal inflammation and choroida neovascularization.

- **Respiratory diseases**

Caffeine is now used as a clinical treatment for respiratory illness, specifically premature new born ailments like apnea and bronchopulmonary dysplasia (BPD).

- **Neurodegenerative diseases**

Among psychoactive stimulants, caffeine is thought to be the most commonly ingested stimulant worldwide. This naturally occurring substance can penetrate the blood brain barrier and based on published research, may stimulate the central nervous system by influencing a number of molecular targets including adenosine receptor antagonism, intracellular calcium mobilization, phosphodiesterase inhibition and GABA receptor inhibition.

SIDE EFFECTS

Many people start every day with caffeine in one form or another to help them feel more alert, energised and focused.

That's not a bad thing for many people, if your overall health is good and you don't have any other health condition, the most common signs you are having too much caffeine include,

- Anxiety, restlessness,
- Having trouble sleeping,
- Experiencing stomach problem or heartburn,
- Dizziness or shakiness
- Rapid heart beat

Caffeine is both a natural product and a drug. It is a mixed bag of good and not so good. If it's working for you, there is no reason to make a change.

TOXICITY

The oral LD50 for caffeine in rats is 192mg/kg. MSDS an acute lethal overdose of caffeine in human is approximately 10-14 gm (equal to 150 -200mg/kg of body weight).

CAFFEINE OVERDOSE

Caffeine overdose can cause seizures because it stimulates the CNS. It should be taken with considerable caution in people with epilepsy or other seizure disorders. Overdose symptoms may include nausea, vomiting, diarrhea and gastrointestinal Disturbance. The world health organization's international classification of disease (ICD-10) includes caffeine intoxication depending on the amount of caffeine ingested. Symptoms may include agitation, anxiety, restlessness, sleeplessness, tachycardia, tremors, psychomotor agitation and in extreme circumstances death. Overdose is more frequent in people who do not consume caffeine on a regular basis but do consume energy drinks.

CONCENTRATION OF CAFFEINE

Your metabolism overall health and body mass all affect how you respond to caffeine .It also depends on how much caffeine you consume in a single serving and weather your

body is acclimated to receiving regular dosages, studies indicate that a daily intake of 400 mg or less of caffeine is suitable for most people.

CONCLUSION

This article aims to describe about the chemical structure and nature of caffeine. How this chemical substance enters human body due to daily consumption of various beverages. As we know caffeine if consumed in excess will cause many health issues, on the other side it also has medicinal value and is used as preventive medicine for many diseases. Thus, the article includes positive and negative effects of caffeine in human body.
