Abstract:

The objective of this paper is to develop an effective robust fuzzy c-means for a segmentation of breast and brain magnetic resonance images. The widely used conventional fuzzy c-means for medical image segmentations has limitations because of its squared-norm distance measure to measure the similarity between centers and data objects of medical images which are corrupted by heavy noise, outliers, and other imaging artifacts. To overcome the limitations this paper develops a novel objective function based standard objective function of fuzzy c-means that incorporates the robust kernel-induced distance for clustering the corrupted dataset of breast and brain medical images. By minimizing the novel objective function this paper obtains effective equation for optimal cluster centers and equation to achieve optimal membership grades for partitioning the given dataset. In order to solve the problems of clustering performance affected by initial centers of clusters, this paper introduces a specialized center initialization method for executing the proposed algorithm in segmenting medical images. Experiments are performed with synthetic, real breast and brain images to assess the performance of the proposed method. Further the validity of clustering results is obtained using silhouette method and this paper compares the results with the results of other recent reported fuzzy c-means methods. The experimental results show the superiority of the proposed clustering results.

Keywords: Brain Images; MLBP, Texture. LMEBP

1. Introduction

Clustering is a form of unsupervised learning that aims to analyze and organize data into groups based on their similarity. For this reason, clustering is widely used in various problem-solving and decision-making applications, such as document retrieval, marketing research, genotype assignment, insurance fraud identification, image segmentation [1]. Over the years, there have been many methods and techniques developed to perform cluster analysis. Most traditional cluster analysis methods are crisp partitioning, in which every given object is strictly classified into a certain group. Hereby, the boundaries among classes are sharply in such partition. However, in practice, the class attributes of most objects are not strict but ambiguous; hence it is not suitable for soft partitioning. Fortunately, the fuzzy set theory proposed [2]. Initially, cluster based medical segmentation like k-mean, fuzzy c-mans algorithms are proposed for medical image segmentation. In recent years, researchers using the feature based algorithms for medical image segmentation [3]. Based on the literature, we motivated to work in the direction of medical image segmentation using feature descriptors [4]. Now, a concise review of the related literature available, targeted for development of our algorithms is given here. Local binary pattern features have emerged as a silver lining in the field of texture retrieval.

Ojala et al. proposed LBP [1] which are converted to rotational invariant for texture classification in [5]. Rotational invariant texture classification using feature distributions is proposed in [8]. The combination of Gabor filter and LBP for texture segmentation [9] and rotational invariant texture classification using LBP variance with global matching [10] has also been reported. Liao et al. proposed the dominant local binary patterns for texture classification [11]. Guo et al. developed the completed LBP scheme for texture classification [12]. LBP operator on facial expression analysis and recognition is successfully reported in [13] and [14]. Xi Li et al. proposed multi-scale heat kernel based face representation, for heat kernels that performs well in characterizing the topological structural information of face appearance. Further, the local binary pattern (LBP) descriptor is incorporated into the multiscale heat kernel face representation for capturing texture information of face appearance [15]. Face recognition under different lighting conditions by the use of local ternary patterns is discussed in [16] where emphasis lays on the issue of robustness of the local patterns. The background modeling and detection using LBP, extended LBP for shape localization and LBP for interest region description has been reported in [17], [18] and [19] respectively. Zhao et al. proposed the local spatiotemporal descriptors using LBP to represent and recognize spoken isolated phrases based solely on visual input [20]. Spatiotemporal local binary patterns extracted from mouth regions are used for describing isolated phrase sequences. Unay et al. proposed the local structure-based region-of-interest retrieval in brain MR images [16]. Yao and Chen proposed the local edge patterns for texture retrieval [21] where LEP value is computed using an edge obtained by applying the Sobel edge detector to intensity gray level and then LEP feature are extracted to describe the spatial structure of the local texture according to the organization of the edge pixels in a neighborhood [22-25].

1.1 Main contributions

The organization of the paper is as follows: In section 1, a brief review of texture features for various applications is given. A concise review of local binary patterns and LMEBP can be visualized in Section 2. Section 3, presents the proposed algorithm for medical image segmentation [70-72]. Further, experimental results and discussions to support the algorithm can be seen in section 4. Conclusions are derived in section 5.

The LBP operator was introduced by Ojala *et al.* [26-28] for texture classification. Success in terms of speed (no need to tune any parameters) and performance is reported in many research areas such as texture classification [29-30], face recognition [31-33], object tracking, bio-medical image retrieval and finger print recognition [34-37].

Given a center pixel in the 3×3 pattern, LBP value is computed by comparing its gray scale value with its neighborhoods based on Eq. (1) and Eq. (2):

$$LBP_{P,R} = \sum_{i=1}^P 2^{(i-1)} \times f(I(g_i) - I(g_c)) \quad (1)$$

$$f(x) = \begin{cases} 1 & x \geq 0 \\ 0 & \text{else} \end{cases} \quad (2)$$

Where $I(g_c)$ denotes the gray value of the center pixel, $I(g_i)$ is the gray value of its neighbors, P stands for the number of neighbors and R , the radius of the neighborhood [6769].

Fig. 1 shows an example of obtaining an LBP from a given 3x3 pattern. The histograms of these patterns extract the distribution of edges in an image [38-40].

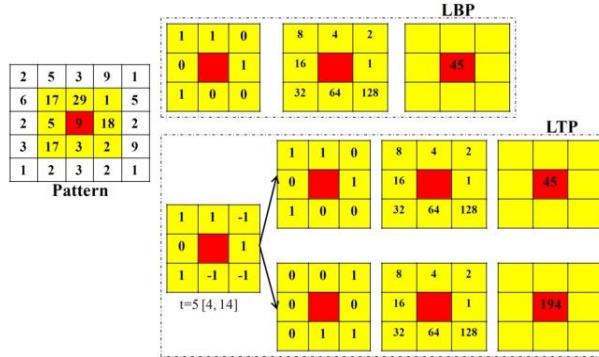

Fig. 1: Example of obtaining LBP and LTP for the 3x3 pattern

Tan and Triggs [41-43] extended the LBP to three valued code called local ternary patterns (LTP), in which gray values in the zone of width $\pm t$ around g_c are quantized to zero, those above (g_c+t) are quantized to $+1$ and those below (g_c-t) are quantized to -1 , i.e., the indicator $f(x)$ is replaced with 3-valued function (Eq. 3) and binary LBP code is replaced by a ternary LTP code as shown in Fig. 1.

$$\bar{f}(x, g_c, t) = \begin{cases} +1, & x \geq g_c + t \\ 0, & |x - g_c| < t \\ -1, & x \leq g_c - t \end{cases} \quad (3)$$

More details about LTP can be found in [44-47].

After computing the LP (LBP or LTP) for each pixel (j, k) , the whole image is represented by building a histogram as shown in Eq. (4).

$$H_{LP}(l) = \sum_{j=1}^{N_1} \sum_{k=1}^{N_2} f(LP(j, k), l); \quad l \in [0, (2^p - 1)] \quad (4)$$

$$f(x, y) = \begin{cases} 1 & x = y \\ 0 & \text{else} \end{cases} \quad (5)$$

Where the size of input image is $N_1 \times N_2$.

In proposed LMEBP [48-50] for a given image the first maximum edge is obtained by the magnitude of local difference between the center pixel and its eight neighbors as shown below:

$$I'(g_i) = I(g_c) - I(g_i); \quad i = 1, 2, \dots, 8 \quad (6)$$

$$i_1 = \arg \left(\max_i \left(|I'(g_1)|, |I'(g_2)|, \dots, |I'(g_8)| \right) \right) \quad (7)$$

Where, $\max(x)$ calculates the maximum value in an array 'x'.

If this edge is positive, assign '1' to this particular center pixel otherwise '0'.

$$I^{new}(g_c) = f(I'(g_{i_i})) \quad (8)$$

$$f(x) = \begin{cases} 1 & x \geq 0 \\ 0 & \text{else} \end{cases} \quad (9)$$

The LMEBP is defined as:

$$LMEBP(I(g_c)) = \{I^{new}(g_c); I^{new}(g_1); I^{new}(g_2); \dots \dots \dots I^{new}(g_8)\} \quad (10)$$

Eventually, the given image is converted to LMEBP image having values ranging from 0 to 511.

After calculation of LMEBP, the whole image is represented by building a histogram supported by Eq. (11).

$$H_{LMEBP}(l) = \sum_{j=1}^{N_1} \sum_{k=1}^{N_2} f(LMEBP(j, k), l); l \in [0, 511] \quad (11)$$

$$f(x, y) = \begin{cases} 1 & x = y \\ 0 & \text{else} \end{cases} \quad (12)$$

Where the size of input image is $N_1 \times N_2$.

Similarly, the remaining seven LMEBPs are evaluated using seven maximum edges (second maximum edge to eighth maximum edge) to obtain eight LMEBP histograms. Hence the feature vector of the proposed method is 8×512 .

For rotational invariant LMEBP, we coded the LMEBP by gathering only the eight neighbors of a center pixel [51-53]. Further the uniform patterns are also considered [54-55]. In this paper, the pattern which has less than or equal to two discontinuities in the circular binary presentation is considered as the uniform pattern and remaining patterns are regarded as non-uniform patterns.

2. Segmentation Algorithm

Input: Image; Output: Retrieval result

1. Load the gray scale image
2. Calculate the LMEBP features from an image.
3. Divide the LMEBP map in to sub blocks.
4. Apply the similarity between the sub blocks.
5. Based on the similarity merge the sub blocks.
6. Form the regions (segments) for final segmentation.

Feature vector for block-1, Q is represented as $f_Q = (f_{Q_1}, f_{Q_2}, \dots \dots \dots f_{Q_{Lg}})$ obtained after the feature extraction [57-61].

Similarly block-2 feature vector $f_{DB_i} = (f_{DB_{i1}}, f_{DB_{i2}}, \dots \dots \dots f_{DB_{iLg}}); i = 1, 2, \dots \dots, |DB|$.

In order to match the sub blocks we used d_l similarity distance metric computed by Eq. (13).

$$D(Q, DB) = \sum_{i=1}^{Lg} \left| \frac{f_{DB_{ji}} - f_{Q_i}}{1 + f_{DB_{ji}} + f_{Q_i}} \right| \quad (13)$$

Where $f_{DB_{ji}}$ is i^{th} feature of j^{th} image in the database $|DB|$.

3. Results and Discussions

In order to verify the effectiveness of the proposed algorithm, experiments were conducted on two brain MRIs [62-66]. The performance of the proposed algorithm is compared with the other existing FCM variant methods in terms of score, number of iterations (NI) and computational time (CT) on OASIS-MRI dataset.

Fig. 2 and Fig. 3 illustrate the segmentation results of the proposed algorithm. Table 1 to Table 6 illustrates the results of proposed algorithm for image segmentation. The results after being investigated, the proposed method outperforms the other existing method in terms of score, number of iterations and time on benchmark database.

4. Conclusions

A novel methodology based on feature descriptors is proposed for medical image retrieval application. For feature extraction LMEBP is used and then merging of sub blocks concept is used for segmentation. The performance of the proposed method is tested on benchmark database. The results after being investigated proposed method outperforms the other existing methods in terms of segmentation score, number of iterations and time.
